

Optimistic Processing of Network Frames to Reduce Latency

## ABSTRACT

5           A system and method in which the server device processes the lower level layers,  
referred to herein as the “network portion”, of a frame substantially in parallel with the  
processing of the application portion of the frame. The application portion of the frame, which  
may include an HTTP request is forwarded to the server application such as a web server, while  
the network portion of the frame is processed. If the processing of the network portion  
10 determines that the frame was mis-delivered or is corrupted, the response to the HTTP request is  
aborted, otherwise the response is processed and returned to the client. By optimistically  
assuming that the request was delivered correctly, the present invention leverages the parallel  
processing capabilities available on many server appliances and improve response time without  
incurring any substantial performance penalty.
